The molecular system is free to rotate and the probability of detecting the molecule in a rotationally excited state depends on the orientation of the molecule with respect to the electric field of the pulse. We denote the orientation of the molecule with R . The X-ray-induced rotationally excited states are denoted by k . In the case of neutral molecules, in general, the molecular angular momentum is a combination of the spin angular momentum and the orbital angular momentum. The effect of anisotropic momentum distribution of the plasma on the scattering probability is investigated. For the corresponding, the parameter k of the Fermi surface becomes very large and is negative. The parameter b of the momentum distribution may be positive. In the extreme case the momentum distribution may have the form factor of a positron of Fermi momentum k_0 . In principle, this should create a maximum in the scattering

probability. We compute the angle-integrated transmission probability, the angle-integrated reflection probability and the angle-integrated scattering cross-section in the plasma as a function of k . At large k also the angle-integrated absorption probability is investigated as a function of the momentum anisotropy of the plasma. We find that the average scattering is enhanced by a factor $O(10)$. For the solar atmosphere, however, which possesses a significant momentum anisotropy, the mean-free-path of the neutrinos is extremely small and it becomes more or less unimportant for the scatterings.

Varshalovich Quantum Theory Of Angular Momentum Pdf 30
